HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

A Second-Order Formulation of Non-Termination

Fred Mesnard, Étienne Payet

Université de La Réunion, EA2525-LIM, Saint-Denis de La Réunion, F-97490, France

Abstract

We consider the termination/non-termination property of a class of loops. Such loops are commonly used abstractions of real program pieces. Second-order logic is a convenient language to express non-termination. Of course, such property is generally undecidable. However, by restricting the language to known decidable cases, we exhibit new classes of loops, the non-termination of which is decidable. We present a bunch of examples.

Keywords: Termination, non-termination, monadic second-order logic.

1. Introduction

In this paper, we recall that second-order logic is a convenient language to express non-termination of while loops, modeled as rules. Such rules are commonly used abstractions of real program pieces, see, e.g., [12] for the Java programming language. Our main contribution is the definition of two new classes of rules, the termination of which is decidable, by restricting the language to known decidable cases, namely S1S and S2S. We also show and illustrate how decision procedures for their weak versions WS1S and WS2S can help proving termination/non-termination.

We organize the paper as follows. Section 2 presents the main concepts we need while Section 3 gives the theoretical results of the paper. Section 4 illustrates the results by means of examples and Section 5 concludes.

2. Preliminaries

We give a quick description of S1S and S2S, see [13] for a more detailed presentation. S1S is the monadic Second-order theory of 1 Successor. Interpretations correspond to finite or infinite words over a given finite alphabet Σ . Terms are constructed from the constant 0 and first-order variables x, y, \dots by application of the successor function $+1$, which is left-associative. We abbreviate n successive applications of $+1$ starting from 0 (i.e., $0 + 1 + 1 + \dots + 1$) to n .

Email addresses: frederic.mesnard@univ-reunion.fr (Fred Mesnard),
etienne.payet@univ-reunion.fr (Étienne Payet)

Atomic formulæ are constructed from terms, second-order variables X, Y, \dots and predicates of the form P_a where $a \in \Sigma$. They have the form $t = t', t < t', t \in X, P_a(t)$ where t and t' are terms. Formulæ are constructed from atomic formulæ, the usual boolean connectives (\vee, \wedge, \dots) and quantification (\forall and \exists) over first and second-order variables. First-order variables are interpreted as elements of \mathbb{N} representing positions in words and second-order variables as subsets of \mathbb{N} . Constant 0 is interpreted as the first position in a word and function $+1$ as the next position. The formula $P_a(t)$ is true in a word w if at position t of w there is character a . WS1S (Weak S1S) is a restriction of S1S where second-order variables are interpreted as *finite* sets only.

S2S is the monadic Second-order theory of 2 Successors. Interpretations correspond to finite or infinite labelled binary trees over a given finite alphabet Σ . Terms and formulæ are constructed as in S1S except that constant 0 is replaced with ε and the successor function $+1$ is replaced with functions $.0$ and $.1$, which are left-associative. We abbreviate successive applications of these functions, for instance $x.0110$ stands for $x.0.1.1.0$, which corresponds to $((x.0).1).1).0$, and 0110 stands for $\varepsilon.0.1.1.0$. First-order variables are interpreted as elements of $\{0, 1\}^*$ representing positions in binary trees and second-order variables as subsets of $\{0, 1\}^*$. Constant ε is interpreted as the root position of a binary tree, $.0$ as the left successor, $.1$ as the right successor and $<$ as the proper-prefix relation (for instance $01 < 0110$ but $00 \not< 0110$). WS2S (Weak S2S) is a restriction of S2S where second-order variables are interpreted as *finite* sets only.

A *rule* has the form $r : \tilde{x} \rightarrow \psi(\tilde{x}, \tilde{y}), \tilde{y}$ where r is the identifier of the rule, ψ is a binary relation and \tilde{x} and \tilde{y} are tuples of distinct first-order variables ranging over a given domain. If r is a monadic rule of the form $x \rightarrow \psi(x, y), y$ and $\psi(x, y)$ is a monadic second-order formula of S1S (S2S) with x and y as free variables, we call r a *monadic* S1S (respectively, S2S) rule. Some examples can be found in Section 4. We define an operational semantics as follows. Starting from a concrete tuple \tilde{x}_0 of elements of the domain, we first check whether there exists a concrete tuple \tilde{x}_1 such that $\psi(\tilde{x}_0, \tilde{x}_1)$. If no such tuple exists, the computation stops. Otherwise, we choose any such tuple \tilde{x}_1 and reiterate. The rule r *loops* if we can find a concrete tuple \tilde{x}_0 starting an infinite computation. If no such tuple exists, r *terminates*.

3. A Second-Order Formulation of Non-Termination

We consider the following second-order formulation of non-termination. Let $r : \tilde{x} \rightarrow \psi(\tilde{x}, \tilde{y}), \tilde{y}$ be a rule.

Definition 1 (recurrence set [8]). We let ϕ_r denote the second-order formula

$$\exists X \begin{cases} \exists \tilde{x} \tilde{x} \in X \wedge & (1) \\ \forall \tilde{x} \exists \tilde{y} (\tilde{x} \in X \Rightarrow [\psi(\tilde{x}, \tilde{y}) \wedge \tilde{y} \in X]) & (2) \end{cases}$$

A recurrence set for r is a set X satisfying ϕ_r .

Condition (1) of Definition 1 simply states that the recurrence set X is not empty. Condition (2) ensures that for any element x of X , there is an element y of X which satisfies the formula $\psi(\tilde{x}, \tilde{y})$ defining the rule r . The existence of a recurrence set is equivalent to non-termination.

Theorem 2 ([8]). ϕ_r is true if and only if r loops.

Proof. We prove both implications.

(\Rightarrow). As ϕ_r is true, we can start by selecting any arbitrary $\tilde{x}_0 \in X$. We know that there exists $\tilde{y}_0 \in X$ s.t. $\psi(\tilde{x}_0, \tilde{y}_0)$. By iterating this process, we construct an infinite computation. Hence r loops.

(\Leftarrow). As there exists \tilde{x}_0 such that r loops, let us consider an infinite computation starting at \tilde{x}_0 : $\tilde{x}_0, \tilde{x}_1, \dots, \tilde{x}_n, \dots$. Let $X = \{\tilde{x}_i | i \geq 0\}$. X is a non-empty set verifying $\forall \tilde{x} \exists \tilde{y} (\tilde{x} \in X \Rightarrow [\psi(\tilde{x}, \tilde{y}) \wedge \tilde{y} \in X])$. Hence ϕ_r holds. \square

The notion of *closed recurrence set* is introduced in [5].

Definition 3 (closed recurrence set). We let ϕ'_r be the second-order formula

$$\exists X \left\{ \begin{array}{l} \exists \tilde{x} \tilde{x} \in X \wedge \quad (1) \\ \forall \tilde{x} \exists \tilde{y} (\tilde{x} \in X \Rightarrow \psi(\tilde{x}, \tilde{y})) \wedge \quad (2) \\ \forall \tilde{x} \forall \tilde{y} ([\tilde{x} \in X \wedge \psi(\tilde{x}, \tilde{y})] \Rightarrow \tilde{y} \in X) \quad (3) \end{array} \right.$$

A closed recurrence set for r is a set X satisfying ϕ'_r .

Let $S_{\tilde{x}}$ denote the set of successors of \tilde{x} with ψ , i.e., the set of \tilde{y} such that $\psi(\tilde{x}, \tilde{y})$ holds. Definition 3 imposes that $\emptyset \neq S_{\tilde{x}} \subseteq X$ for any \tilde{x} in X . Hence, we *must* stay in X when applying ψ to \tilde{x} . In contrast, Definition 1 requires that $S_{\tilde{x}} \cap X \neq \emptyset$, i.e., we *can* stay in X when applying ψ to \tilde{x} . Therefore, closed recurrence sets are recurrence sets but we also have that recurrence sets always contain closed recurrence sets.

Theorem 4 ([5]). If there is a recurrence set X for r then there exists a rule $r' : \tilde{x} \rightarrow \psi'(\tilde{x}, \tilde{y}), \tilde{y}$ with $\psi' \Rightarrow \psi$ and $X' \subseteq X$ such that X' is a closed recurrence set for r' .

The second-order formula ϕ_r is a necessary and sufficient condition for non-termination of at least one of the computations r can generate. Symmetrically, $\neg\phi_r$ is true if and only if for every value \tilde{x}_0 , any computation starting at \tilde{x}_0 halts. As such a problem is in general undecidable (see, e.g., [2]), it follows that ϕ_r is not computable. However, when the second-order logic is restricted to decidable cases, we obtain classes of rules for which the termination/non-termination property is decidable.

Theorem 5. Termination of a monadic S1S or S2S rule is decidable.

Proof. The monadic second-order logics S1S and S2S are decidable [4, 11] and so is ϕ_r for a monadic S1S or S2S rule r . If ϕ_r is true then r loops else r terminates. \square

Weak versions of these logics, where second-order variables range over *finite* sets, are also decidable and decision procedures have been implemented (see, e.g., MONA [9]). Let r be a monadic S1S or S2S rule.

Corollary 1. *Decision procedures for WS1S and WS2S provide computable sufficient conditions for proving non-termination of r in the corresponding structure.*

Proof. If such a decision procedure states that ϕ_r is true, then we know that there exists a non-empty finite set X such that ϕ_r holds. Hence r loops. \square

Note that if the decision procedure states that ϕ_r is false, then there is no finite set X satisfying ϕ_r but an infinite set X satisfying ϕ_r may exist. Hence we cannot conclude, except in the following case.

Corollary 2. *When we know that the set of points which can start a computation from r is finite, decision procedures for WS1S and WS2S also decide termination of r in the corresponding structure.*

Proof. If a decision procedure states that ϕ_r is true, then by Corollary 1 r loops. Else it states that ϕ_r is false. So there does not exist a finite set X satisfying ϕ_r . As X cannot be infinite by hypothesis, it means that there does not exist a set X such that ϕ_r holds. Hence r terminates. \square

Note that the condition of Corollary 2 can be decided in WS1S as it can be stated as $\exists m \forall x (x > m \Rightarrow \neg \exists y \psi(x, y))$. However Example 8 shows that it does not decide termination.

4. Examples

Example 6 (S1S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (3 < x \wedge x < 10 \wedge y < x) \vee (x < 3 \wedge y = x + 1)$$

The set of points which can start a computation from r is finite: $\{x \in \mathbb{N} \mid x \neq 3 \wedge x < 10\}$. MONA tells us that ϕ_r is false. By Corollary 2, r terminates. \square

Example 7 (S1S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (3 < x \wedge y < x) \vee (x < 4 \wedge y = x + 1)$$

MONA reports that ϕ_r is true, with a computed satisfying $X = \{3, 4\}$. Indeed for any $x \in X = \{3, 4\}$, there is a y in X such that $\psi(x, y)$ holds: if $x = 3$, take $y = 4$ and if $x = 4$, $y = 3$. Note that the set X is not unique, as ϕ_r is also true for, e.g., $X = \{2, 3, 4, 2014\}$. By Corollary 1, r loops. \square

Example 8 (S1S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (x < y)$$

Although MONA tells us that there is no finite X satisfying ϕ_r , as the set of points which can start a computation is infinite, we cannot apply Corollary 2. Indeed, taking $X = \mathbb{N}$ shows that ϕ_r is true. Hence by Theorem 2, r loops. Note that any decision procedure for S1S will prove that ϕ_r is true. \square

Example 9 (S1S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (y < x)$$

MONA reports that there is no finite X satisfying ϕ_r . As the set of points which can start a computation is infinite, we cannot apply Corollary 2. Assume that ϕ_r is true. So there is a non-empty $X \subseteq \mathbb{N}$ satisfying ϕ_r . Let e be its least element. Condition (2) of Definition 1 states that there exists d in X such that $d < e$, which contradicts that e is the least element of X . Hence ϕ_r is false, as should be shown by any decision procedure for S1S. By Theorem 2, r terminates. \square

Example 10 (S1S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (\forall X (x \in X \wedge \psi'(X)) \Rightarrow y \in X)$$

with

$$\psi'(X) = (\forall z z \in X \Rightarrow z + 1 \in X)$$

We have $\psi'(X)$ is true if and only if X is closed by application of the successor function $+1$. So, $\psi(x, y)$ is true if and only if $x \leq y$. MONA reports that ϕ_r is true, with a computed satisfying $X = \{0\}$. By Corollary 1, r loops. \square

Example 11 (S2S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (y = x.1 \vee x = y.1)$$

The set $X = \{\varepsilon, 1\}$ is not empty and for any x in X there is a y in X such that $\psi(x, y)$ holds. So ϕ_r is true (also shown by MONA). By Corollary 1, r loops.

Note that X is a recurrence set for r which is not closed. Indeed, $1 \in X$ and $\psi(1, 1^2)$ holds with $1^2 \notin X$. Hence, condition (3) of Definition 3 does not hold. By Theorem 4, there must exist $r' : x \rightarrow \psi'(x, y), y$ with $\psi' \Rightarrow \psi$ and $X' \subseteq X$ such that X' is a closed recurrence set for r' . For

$$\psi'(x, y) = (x \neq 1 \wedge y = x.1) \vee x = y.1 \quad \text{and} \quad X' = X$$

we have that $\psi' \Rightarrow \psi$, $X' \subseteq X$ and X' is a closed recurrence set for r' . \square

Example 12 (S2S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\begin{aligned} \psi(x, y) = & \\ & (\exists z x < 0^4 \wedge x = z.0 \wedge y = z.1) \vee \\ & (\exists z z.01 \leq x \wedge y = z.11) \vee \\ & (x = 1^2 \wedge y = 0^3) \end{aligned}$$

The set $X = \{1^2, 0^3, 0^21, 01^2\}$ is not empty and for any x in X there is a y in X such that $\psi(x, y)$ holds. Hence ϕ_r is true (also shown by MONA), so r loops. Note that X is a closed recurrence set for r . \square

Example 13 (S2S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\begin{aligned} \psi(x, y) = & \\ & (\exists z \ x = z.0 \wedge y = z.1) \vee \\ & (\exists z \ x = z.1 \wedge y = z.10) \end{aligned}$$

The infinite set $X = \{0, 1, 10, 11, 110, 111, \dots\} = 1^*(0 + 1)$ is not empty and for any x in X there is a y in X such that $\psi(x, y)$ holds. Hence ϕ_r is true, as should be shown by any decision procedure for S2S. So r loops. Note that X is a closed recurrence set for r . \square

Example 14 (S2S). Consider $r : x \rightarrow \psi(x, y), y$ where

$$\psi(x, y) = (\forall X \ (x \in X \wedge \psi'(X)) \Rightarrow y \in X)$$

with

$$\psi'(X) = (\forall z \ z \in X \Rightarrow (z.0 \in X \wedge z.1 \in X))$$

We have $\psi'(X)$ is true if and only if X is closed by application of the successor functions $.0$ and $.1$. So, $\psi(x, y)$ is true if and only if $x \leq y$. MONA reports that ϕ_r is true, with a computed satisfying $X = \{\varepsilon\}$. By Corollary 1, r loops. \square

5. Related Works and Conclusion

Recurrence sets were first introduced in [8] where ψ denotes any binary relation. Two symbolic analyses are presented in this paper for constructing such sets: a bitwise analysis, which assumes that the state space is finite and encoded using Boolean variables, and a linear arithmetic analysis, which assumes that the program transitions can be represented as rational linear constraints. In contrast to our work, no second-order formulation is considered in this paper.

Let us now focus on termination-decidable classes of rules. In [7], the authors present a decision procedure for an arbitrary rule $\tilde{x} \rightarrow \psi(\tilde{x}, \tilde{y}), \tilde{y}$ where $\psi(\tilde{x}, \tilde{y})$ is a conjunction of equality constraints over rational trees. In [10, 6, 1], one finds variations of a decision procedure for finite sets of rules $\tilde{x} \rightarrow \psi(\tilde{x}, \tilde{y}), \tilde{y}$ where $\psi(\tilde{x}, \tilde{y})$ is a conjunction of constraints $x > y$ or $x \geq y$ over a well-founded domain (such as the natural numbers) or the integers. Generalizing [14], termination of an arbitrary deterministic linear loop is shown decidable in [3] over the integers, the rationals, and the reals. To the best of our knowledge, termination of a non-deterministic linear loop remains an open problem.

Summarizing the paper, we have seen that second-order logic is a convenient language to express non-termination as a necessary and sufficient condition. Such a condition is in general undecidable. By restricting the language to the decidable cases S1S and S2S, we have defined two new classes of rules, the

termination of which is decidable. Finally, we have shown that the weak versions of these logics provide sufficient conditions for termination and non-termination of such rules.
