HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Seroprevalence of Dengue and Chikungunya Virus Antibodies, French Polynesia, 2014–2015

Maite Aubry, Anita Teissier, Michael Huart, Sébastien Merceron, Jessica Vanhomwegen, Mihiau Mapotoeke, Teheipaura Mariteragi-Helle, Claudine Roche, Anne-Laure Vial, Sylvianne Teururai, Sébastien Sicard, Sylvie Paulous, Philippe Desprès, Jean-Claude Manuguerra, Henri-Pierre Mallet, Allison Imrie, Didier Musso, Xavier Deparis, Van-Mai Cao-Lormeau

We investigated dengue and chikungunya virus antibody seroprevalence in French Polynesia during 2014–2015. Dengue virus seroprevalence was $\approx 60\%$ among schoolchildren and $>83\%$ among the general population; chikungunya virus seroprevalence was $<3\%$ before and 76% after Zika virus emergence (2013). Dengue virus herd immunity may affect Zika virus infection and pathogenesis.

In French Polynesia, the only recognized actively circulating arboviruses were the 4 dengue viruses (DENV; family *Flaviviridae*, genus *Flavivirus*) (1,2) until Zika virus (family *Flaviviridae*, genus *Flavivirus*) emerged there in 2013 (3), followed by chikungunya virus (family

Togaviridae, genus *Alphavirus*) in 2014 (4). Serosurveys conducted among blood donors in French Polynesia during 2011–2013, before these outbreaks, confirmed the absence of Zika and chikungunya virus circulation and assessed DENV antibody seroprevalence at $\approx 80\%$ at that time (5,6). Another study conducted after the emergence of Zika virus showed Zika virus antibody seroprevalence rates $\pm 95\%$ CIs to be $49\% \pm 7\%$ among the general population and $66\% \pm 5\%$ among schoolchildren in 2014 and $22\% \pm 6\%$ among the general population in 2015 (7). We report seroprevalence of antibodies against the 4 DENVs and chikungunya virus in French Polynesia in 2014–2015 and discuss the possible role of anti-DENV herd immunity on Zika virus infection and pathogenesis.

The Study

To assess antibody seroprevalence against DENV types 1–4 and chikungunya virus in the population of French Polynesia, we conducted 3 cluster samplings (7). During February–March 2014, we sampled 196 participants from the general population of the 8 most inhabited islands of the 5 French Polynesia archipelagos: Tahiti and Moorea (Society), Rangiroa and Makemo (Tuamotu), Nuku Hiva and Hiva Oa (Marquesas), Rurutu (Australis), and Rikitea (Gambier). To better estimate seroprevalence of antibodies against these viruses among children, during May–June 2014, we recruited 476 schoolchildren from primary and high schools on the most populous island (Tahiti). To increase accuracy of seroprevalence data for DENVs and assess postoutbreak chikungunya virus seroprevalence, during September–November 2015, we sampled 700 members of the general population from the most inhabited archipelago (Society). All participants were asked whether they had had symptoms suggestive of past dengue disease. Because chikungunya virus emerged in French Polynesia in late 2014, symptoms suggestive of past disease were recorded only from participants sampled in 2015. The study was conducted in accordance with the French Polynesia Ethics Committee (agreement 60/CEPF_06/27/2013).

We performed detection of DENV and chikungunya virus IgG on blood samples collected in 2014 by using a recombinant-antigen–based indirect ELISA (5,6) and tested samples collected in 2015 by microsphere

immunoassay (MIA) (8) using the same recombinant antigens as for the ELISA. Among the samples collected in 2015, we selected 20 to be a representative panel of the different antibody profiles found by MIA and tested them for neutralizing antibodies against each dengue, chikungunya, and Zika virus (8). We analyzed data by using GraphPad Prism version 6.03 software (<https://www.graphpad.com/>) and the Fisher exact test. We set significance at $p < 0.05$.

Overall seropositivity rates for antibodies against ≥ 1 DENV were $96\% \pm 3\%$ among the general population and $60\% \pm 5\%$ among schoolchildren in 2014 and $83\% \pm 3\%$ among the general population in 2015 (Table 1). Seroprevalence of DENV antibodies did not differ significantly between archipelagos, except for DENV-3, which differed between Society ($76\% \pm 18\%$) and Austral-Gambier ($53\% \pm 15\%$) Islands ($p = 0.034$). In all 3 groups of participants, we found the highest seropositivity rates for DENV-1 antibodies and the lowest for DENV-2. Seropositivity rates in 2014 and 2015 for all DENV antibodies were significantly lower for schoolchildren (median age 11 years) than for the general population (median age 41 years in 2014 and 43 years in 2015) (all $p < 0.0001$). Seroprevalence of chikungunya virus antibodies was $3\% \pm 3\%$ among the general population and $1\% \pm 1\%$ among schoolchildren in 2014 and $76\% \pm 5\%$ among the general population in 2015 after the outbreak.

According to information provided by a questionnaire, the percentages of asymptomatic DENV infections were $65\% \pm 7\%$ among the general population and $81\% \pm 5\%$ among schoolchildren in 2014 and $51\% \pm 4\%$ among the general population in 2015. The percentage of asymptomatic chikungunya virus infections in participants recruited in 2015 was $13\% \pm 2\%$. Among the 20 samples positive by MIA for IgG against DENV-1–4 and chikungunya virus in this study and against Zika virus in the previous serosurvey (7), the proportions showing neutralizing activity were 8/9 (89%) for DENV-1, 5/5 (100%)

for DENV-2, 6/6 (100%) for DENV-3, 6/6 (100%) for DENV-4, and 7/8 (88%) each for chikungunya and Zika viruses (Table 2).

Conclusions

The finding of DENV IgG in $>80\%$ of the general population sampled in 2014 and 2015 corroborates past high transmission rates for these viruses in French Polynesia (1,2,6,9). The lower seropositivity rates for antibodies against DENVs among children is consistent with seroprevalence rates for antibodies against viruses endemic to the region, which are expected to increase with duration of exposure (6). Finding the highest seroprevalence rate against DENV-1 in the general population and schoolchildren is consistent with the long-term circulation of this virus in French Polynesia during 2001–2009 and since 2013 (1,9). DENV-2 has not circulated in French Polynesia since 2000 (9), which is consistent with the lowest seroprevalence rate against this virus. The reduced population immunity against DENV-2 coupled with the circulation of this virus in neighboring Pacific Islands and detection of imported infections in travelers entering French Polynesia from Vanuatu in February 2017 (9) indicates that French Polynesia is at risk for a new epidemic. Although seroprevalence rates for antibodies against DENVs are consistent with epidemiologic data, bias associated with the presence of cross-reactive antibodies produced during a previous flavivirus infection could have resulted in detection of antibodies against viruses to which the persons were never exposed. The proportion of asymptomatic DENV infections assessed in this study seems to be consistent with reported rates (10). However, because the questionnaire asked about clinical manifestations suggestive of past DENV infection over a lifetime or during time spent in French Polynesia, the estimates may be strongly limited by recall bias.

The low seroprevalence rates for chikungunya virus antibodies for the general population ($3\% \pm 3\%$) and

‡Results from Aubry et al. (7).

schoolchildren ($1\% \pm 1\%$) in 2014 corroborate previous findings for blood donors sampled during 2011–2013 (3%) (5), suggesting that this virus did not actively circulate in French Polynesia before 2014. The seroprevalence rate for the general population in 2015 ($76\% \pm 5\%$) was higher than the initial estimate of 25% of chikungunya virus infections, which was based on the number of patients who sought medical care during the outbreak (5). The rate of asymptomatic chikungunya virus infections identified in this study ($13\% \pm 2\%$) was comparable to rates reported by other countries (10).

Chikungunya virus antibody seroprevalence was much higher ($76\% \pm 5\%$) than Zika virus antibody seroprevalence for the general population in 2015 ($22\% \pm 6\%$) (7), despite the fact that both were virgin soil outbreaks occurring at the same place during 2 consecutive years (5,6). This discrepancy could be the result of distinct vector competence for Zika and chikungunya viruses in French Polynesia, as demonstrated in local mosquito species (11,12). Another possible explanation is that past exposure of the population to dengue viruses, as corroborated by the high level of anti-DENV neutralizing responses detected in samples collected in 2015, may have provided cross-protection against Zika virus infection (13). However, the occurrence of many cases of Guillain-Barré syndrome and Zika virus infection–associated congenital abnormalities (8,14) might also suggest that Zika virus immunopathogenesis is enhanced in the setting of high seroprevalence of DENV antibodies (15).

Acknowledgments

We are grateful to Rémy Michel for his participation in the development of the sampling protocols and to Eliane Mama, Sylvia Fontanel, and Jean-Paul Pescheux for their help collecting blood samples. We also thank the staff from the Ministries of Health and Education of French Polynesia and from the municipalities selected for the study for their support in recruiting participants and collecting blood samples. We especially thank everyone who volunteered in this study.

This study received grants from the Contrat de Projet Etat-Pays (convention no. 7331/MSS/DSP du 31/08/12 modifiée) and from the French Government Investissement d'Avenir Programme (Labex Integrative Biology of Emerging Infectious Diseases grant no. ANR-10-LABX-62-IBEID).

About the Author

Dr. Aubry is a research scientist at the Institut Louis Malardé, Tahiti, French Polynesia. Her research focuses on the epidemiology in the Pacific region and genetic evolution of various arboviruses, including dengue, Zika, chikungunya, and Ross River viruses.
