HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
MODELING SPATIAL POPULATION DYNAMICS OF GREEN TURTLE (CHELONIA MYDAS) IN THE SOUTHWEST OF INDIAN OCEAN

“Understanding green turtle population dynamics using an Individual Based Model”

More than twenty years of active research on green turtle (Chelonia mydas) in the South West Indian Ocean (SWIO) have contributed to improve the knowledge of the species biology and ecology. However, lots of gaps still remain regarding the links between the main behavioral processes: alimentation, reproduction and migration, while shifts in these processes at individual scale have major impacts at population scale. On this basis, we have started implementing a spatially explicit individual-based model (IBM) to assess population dynamics of the green turtle in the SWIO. Our simulation experiment aims to unify, in a single model, alimentation, navigation and reproduction processes of the biological cycle. Implementing these constraints in an integrative individual-based model will lead to a better understanding of how it affects population dynamics at the end.

1/ An integrative approach

“Field data as the basis for parameterization and validation of the model”

Active research programs in the SWIO have generated and are still generating a large number of data focused on green turtle that are integrated into the model:

(1) Recent nesting population status and seasonality based on long-term beach tracks monitoring started in 1985
(2) Nest parameters and activity based on yearly nest monitoring and incubation temperature since 2006.
(3) Regional genetic structure known for the SWIO
(4) Physiological studies conducted on captive and free-living individuals since 2007
(5) Identified adult migration routes and juveniles open sea behavior, using at least 140 satellite tracks deployed from 2004 to 2011
(6) Oceanographic data such as currents or sea surface temperature retrieved from physical models as well as regional fisheries data from RFMOs.

This entire set of collected data acts as the basis for realistic parameterization and validation of the model.

2/ Individual Based Modeling

“A suitable tool to model green turtle population dynamics in the light of individual traits and local interactions”

Individual-based models aim to understand ecological systems from the properties of individuals that constitute that system. They are helpful when global properties emerge from individual singularities and local interactions. Regarding the complex biological cycle of green turtles and the variability in individual traits, individual-based modeling appears to be the most suitable method to assess:

- How important is the role played by alimentation, reproduction and migration in green turtle population dynamics
- How these three processes interact and constrain each other
- How sensitive they are regarding environment variability

INDIVIDUAL-BASED MODEL

> Study area

South West Indian Ocean countries. Main surveyed spots are shown in red (from West to Est) : Europa, Juan de Nova, Mohéli, Nosy Iranja, Glorieuses, Tromelin, Réunion.

> Individual constraints

Local interactions and local environmental conditions constrain the main processes of the biological cycle. Implementing these constraints in an integrative individual-based model will lead to a better understanding of how it affects population dynamics at the end.
