## Abstract

---

We describe NTI+cTI, our logic programming termination analyzer that took part in the Termination Competition in 2022 and 2023 and won first place both years. The tool is built from two separate components, NTI for *Non-Termination Inference* and cTI for *constraint-based Termination Inference*, plus an overall main process. The source code is available on GitHub.

**2012 ACM Subject Classification** Theory of computation → Automated reasoning

**Keywords and phrases** Termination, Non-termination, Logic Programming

## 1 NTI

NTI [9] is fully written in Java. It performs automated non-termination proofs of logic programs. It implements a technique that consists in unfolding [6] the program under analysis and in checking whether the produced unfolded clauses satisfy some non-termination criteria [11]. When a proof is successful, NTI provides an example of a non-terminating query. Two kinds of criteria are used.

- The first kind [11] relies on an extension of the “is more general than” relation. It is able to detect infinite derivations that consist of the repeated application of the same sequence  $\omega$  of clauses, *i.e.*, of the form  $Q_0 \Rightarrow_{\omega} Q_1 \Rightarrow_{\omega} \dots$ . If the body of an unfolded clause is more general than the head up to some predicate arguments in *neutral position*, then non-termination is detected; more precisely, every query obtained from replacing the neutral arguments of the head with ground terms is non-terminating. So, if such a non-terminating query belongs to the mode of interest then the proof is successful.
- The second kind [10] is able to detect infinite derivations that rely on two sequences  $\omega_1$  and  $\omega_2$  of clauses, *i.e.*, that have the form  $Q_0 (\Rightarrow_{\omega_1}^* \circ \Rightarrow_{\omega_2}) Q_1 (\Rightarrow_{\omega_1}^* \circ \Rightarrow_{\omega_2}) \dots$ . It consists in detecting pairs  $(c_1, c_2)$  of unfolded clauses of a particular form. Intuitively,  $c_1$  and  $c_2$  are mutually recursive and, in  $c_1$ , a context is removed from the head to the body while, in  $c_2$ , it is added again.

## 2 cTI

Termination analysis starts with applying termination inference as presented in [8]<sup>3</sup>. If the mode given in the moded query of interest of the analyzed program implies the inferred termination condition, termination is ensured. This first analysis relies on the *term-size* norm to abstract the logic program and on linear ranking functions, see e.g., [3] for a review. If necessary, termination inference is restarted using the same tool but by combining both the *term-size* norm and the *list-size* norm, as proposed in [5]. Combining these two norms

doubles the arity of each predicate, hence increases the analysis time so we use it in a second step.

In case these first attempts fail, we switch to `BINTERM`, the termination analyzer we've built for Java bytecode termination analysis [12]. `BINTERM` includes various termination tests: linear and eventual ranking functions [2], multi-dimensional linear ranking [1] and the size-change principle [7]. `BINTERM` analyzes binary Constrained Horn Clauses. Here how we map the original moded query and the original logic program to a binary Constrained Horn Clauses. The original logic program goes through a tabled left-to-right top-down mode analysis starting from the original moded query of interest. An abstract numeric constraint logic program is built using the term-size norm. A numerical model is computed [4]. From these three pieces, a binary Constrained Horn Clauses program is created by a tabled left-to-right top-down interpreter, which keeps only the input arguments of the predicates. Finally, this binary Constrained Horn Clauses program is analyzed by `BINTERM`.

Again, if necessary, a similar analysis is done by combining both the term-size and the list-size norms.

At last resort, a left-to-right top-down meta-interpreter with occurs-check computes a time-bounded SLD tree for the most general query. If the tree is complete and because we deal with logic programs, *any* query from the set of concrete queries abstracted by the original moded query terminates. This result does not hold for Prolog.

Otherwise, the termination analyzer cannot conclude.

### 3 NTI+cTI

The main process of our analyzer performs non-termination and termination analyses in parallel. It launches a thread that runs NTI and another thread that runs cTI. If one thread terminates successfully then the other one is stopped. Our analyzer took part in the Termination Competition [13] in 2022 and 2023 and won first place both years in the “logic programming” category.
